Integrating housing costs into the inflation measure: Focus on Belgium

by J. Jonckheere

Integrating housing costs into the inflation measure: Focus on Belgium

J. Jonckheere*

Introduction

The ECB launched a strategy review in January 2020, in order to make sure its monetary policy strategy is fit for purpose. In preparation for this, the ECB, together with the national central banks of the euro area, held listening events to involve the public at large in a dialogue with the European monetary authorities. Rising house prices appeared to be one of the main concerns expressed by participants. The ECB monitors the harmonised index of consumer prices (HICP) for its monetary policy, but that measure only includes a small part of housing costs, that is rent, energy costs and small repairs (for which materials can typically be found in DIY stores). Larger but one-off costs such as purchase of a dwelling and stamp duty (called registration duties in Belgium) are not (yet) considered.

Even though these costs are not part of the official HICP, the fact that consumers consider house prices when shaping their quantitative perceptions (Zekaite 2020) can be one of the reasons why inflation perceptions in the euro area are often higher than the actual observed inflation (ECB, 2021a). In order to have a more representative inflation measure, the ECB reconsidered the options of taking housing prices into account in the HICP.

The debate on whether or not to take on board housing prices in a consumer price index dates back to earlier strategy reviews (for instance the one in 2003). To prepare for the eventuality, it was decided to start compiling an owner-occupied house price index (OOHPI). It was published for the first time by Eurostat in 2016, using data back to 2005 for a couple of countries (such as Belgium), and in 2010 for most euro area countries. The ECB Governing Council felt that this OOHPI largely follows the HICP principles, such as the exclusion of transactions between households, measuring only actual monetary transactions, etc.

Note that this whole article is on the harmonised index of consumer prices (HICP). Belgium also has its own national consumer price index (NCPI), from which the health index¹ is derived. Integrating owner-occupied housing costs in the NICP is not being considered at the moment.

* The author thanks Ken van Loon (Statistics Belgium) for his valuable comments and suggestions.

¹ The health index is the national consumer price index excluding alcoholic beverages, tobacco products and motor fuels.

1. Strategy review

The previous ECB strategy review dates from 2003, and ever since, the euro area economy and the global economy have been undergoing structural changes. So, the ECB launched a new strategy review in 2020. Many subjects were tackled, such as whether the inflation measurement (by the HICP) is still accurate, if the price stability objective of close to but below 2 % is still relevant, what are the new monetary policy instruments and their possible undesired side effects, how will climate change affect the ECB's role, etc. In this article, the focus will be on inflation measurement.

Generally speaking, the inflation target of “below, but close to, 2 % in the medium term” has not been reached¹. One of the things the strategy review investigated was whether the inflation measurement is accurate. Is the HICP still an appropriate criterion for measuring consumer price inflation? Is there any significant measurement bias in the HICP? Are goods and services quality improvements correctly taken into account in the HICP? Some detailed answers to these questions can be found in the Strategy Review Occasional Papers published on the ECB website², but broadly speaking, it has been confirmed that the HICP methodology has been improved significantly since 2003 and it remains the appropriate price measure for assessing achievement of the price stability objective.

Actual inflation has been lower than was perceived by households. More specifically, consumer expectations and perceptions tend to co-move with the actual inflation rates, but the expectations/perceptions are often significantly higher (ECB, 2021a). Generally, a consumer's inflation perception or expectation is related to his or her socio-economic background: young people or females, those who have lower levels of formal education, or those that belong to lower-income groups, tend to have higher inflation perceptions (ECB, 2021a). The dispersion between actual inflation and inflation perceptions might be caused notably by the fact that consumers also bear in mind residential property prices when they think of price inflation (Zekaite, 2020). In fact, house prices have increased more rapidly than the HICP index. In Belgium, house prices rose each year by about 3.6 % on average between 2006 and 2021³, while the HICP increased by an average rate of 1.8 % over the same period. In the euro area, house prices increased each year by 2.3 % on average, and the HICP by 1.5 % over 2006-2021Q3. In preparation for the 2020 strategy review, the ECB and the national central banks, including the NBB, held virtual listening events, during which the public was questioned on a set of topics. It appeared that in Belgium, about 57 % of the respondents signalled housing as a vital category for which they feel the effects of price changes (Wauters, 2021); a finding that was also observed for the euro area in general.

To make the inflation rate as representative as possible for households, the ECB Governing Council has therefore decided to work with Eurostat on the integration of owner-occupied housing costs into the HICP. As a result, a more representative index should bring the inflation perceptions more in line with the actual measure of inflation and should therefore strengthen monetary policy credibility.

2. Housing costs currently in the HICP

The total HICP index is disaggregated into sub-categories, based on the COICOP classification (Classification of Individual Consumption according to Purpose). It classifies 12 major components, such as 01. Food and non-alcoholic beverages, 02. Alcoholic beverages and tobacco products, 03. Clothing and shoes, etc. (for a breakdown, see Annex 1).

¹ In the strategy review 2020, it was decided that the inflation target of “below, but close to, 2 % in the medium term” would change to “2 % in the medium term”. That is, the economic landscape has changed, with a “too-low-for-too-long” inflation environment. Therefore, both upward and downward deviations from the 2 % target are now considered to be equally undesirable.

² https://www.ecb.europa.eu/pub/html/strategy_review.en.html

³ Based on the Eurostat's House Price Index (containing both existing and new dwellings), with data up to 2021Q3.

Table 1

COICOP category 4: disaggregation

COICOP	Name	Currently in HICP	Weight in %, 2021 (BE)
04	Housing, water, electricity, gas and other fuels	Yes	17.2
04.1	Actual rentals for housing	Yes	8.0
04.2	Imputed rentals for housing	No	n.
04.3	Maintenance and repair of the dwelling	Yes	0.5
04.4	Water supply and miscellaneous services related to the dwelling	Yes	2.0
04.5	Electricity, gas and other fuels	Yes	6.6

Source : Eurostat.

The fourth category is called “housing, water, electricity, gas, etc.”. In other words, this is the category that currently represents house-related costs. One of the sub-categories is housing rent (04.1). It concerns private and social dwellings rentals, and garages and student residence rentals.

The COICOP classification foresees a category “04.2 imputed rentals for housing”, which represents a theoretical rental price for the homeowner who lives in his/her own house, but this category does not exist in the HICP. The main reason for this is that this computed rent index would be compiled based on non-monetary transactions, which is not in line with the current HICP legal framework. Nonetheless, according to the national accounts¹, this category represents about 12 % of total consumer spending in Belgium.

Some euro area countries (such as the Netherlands, Germany) do include imputed rentals for housing in their national consumer price index. The US also has this category in its target consumer price index.

Currently, the HICP includes only a small share of maintenance costs. That is, COICOP category 04.3 covers material costs of “Regular maintenance and repair of the dwelling”. The source of these data are mainly Do-It-Yourself stores, and it covers painting material, cement, shower heads, smoke detectors, but also plumbing, carpenter and electrician services, etc. In short, it is the type of chores that is commonly carried out by both tenants and by owners. More substantial repairs, such as wall re-plastering or roof repair, typically carried out by homeowners, are regarded as intermediate consumption in the production of housing services, which fall outside the scope of the HICP (UNSTATS, 2018). Evidently, house purchases or registration duty fees are not represented in the actual HICP either.

But, utility costs such as water supply (04.4) and electricity, gas and other fuels (04.5) are included in the HICP.

3. Including owner-occupied housing in the HICP

3.1 How? Principles of the two approaches considered

It has been confirmed by the most recent strategy review that the HICP remains the best target measure of consumer price inflation for monetary policy. Still, the ECB's Governing Council has recommended including owner-occupied housing costs, since it would make the inflation measure more representative. Including housing

¹ Consumption expenditure of Belgian households (domestic) on average over 2016-2020.

costs in the HICP should nevertheless be done very carefully, respecting the HICP principles. Two different approaches can be considered for this purpose: the net acquisition approach or the rental equivalence approach. Both are presented below.

3.1.1 Rental equivalence approach

Via this approach, a fictitious rental amount is estimated for house owners who live in their own home. That is the “imputed rent” they would pay if they rented the house. Some euro area countries, such as the Netherlands and Germany, take into account owner-occupied housing via the rental equivalence approach in their national CPI. In the US, too, imputed rent is included in their two target inflation rate indices (the US Consumer Price Index and the Personal Consumer Expenditures Index).

The strategy review concluded that the rental equivalence approach is the least suitable of the two approaches considered, as it is based on fictitious rent figures. The HICP requires actual monetary transactions to take place. Besides this, the rental market in a country needs to be large enough to be able to compute a reliable data series on imputed rent figures. This might be a problem in euro area countries with small rental markets, or where the rental market is segregated from that for owned dwellings (ECB, 2021b). That is, prices of comparable rental properties have to be used to estimate owner’s equivalent rent (OER) for owner-occupied houses. Lastly, rent stickiness is common in many euro area countries. That is, regulations/contractual clauses prevent existing contracts from putting up the rent (Hoeberichts and Zekaite, 2020). That is also the case in Belgium; existing rental contracts are usually only adjusted in line with the health index. As a result, new rental contracts might reflect housing market conditions much better than existing contracts, but the former are by far less numerous. Just like in the euro area, the inflation rate of housing rent in Belgium is rather flat and does not reflect house price cycles.

Statistics Belgium improved the methodology for private rentals significantly in January 2020, which had an upward impact on year-on-year inflation over twelve months. Before, about 2 000 tenants, taken from rental contracts registered in the FPS Finance General Administration of Patrimonial Documentation (GAPD) database, were questioned on their housing rent. The inconvenience of that methodology was that there was a low

Chart 1

Housing rent versus the house price cycle

(year-on-year changes of the quarterly index, in %)

Source: Eurostat.

Note: The House Price Index by Eurostat consists of new dwellings and existing dwellings, and therefore shows price increases in the total real estate market. As it also captures transactions on the secondary market, it differs from the owner-occupied house price index (see below).

response, and when a tenant was replaced, the new tenant would not always answer the questionnaire. Consequently, new contracts (that are in fact the biggest source of rent price increases) were not covered. Since 2020, the full GAPD database has been used, so coverage is much broader. This also implies that new contracts are better captured, which is why there has been an upward impact of the introduction of the new methodology on the housing rent inflation rates and there is more volatility in the housing rent index than before. In any case, it is clear that the rent figures do not (entirely) co-move with the housing cycle, which implies that the rental equivalence approach would not fully capture the housing cycle.

3.1.2 Net acquisition approach

The net acquisition approach measures purchase costs of dwellings and other costs that are related to home ownership. The ECB Governing Council has deemed this measure to be most in line with the HICP principles. First, it is based on actual monetary transactions, which is a necessary condition to be in the HICP. Second, the “net” part of that approach refers to the fact that only transactions between the household sector and another sector are taken into account. In other words, transactions between households are not considered. This “net” principle is applied for all the categories in the HICP and can be illustrated by other examples of (semi-durable) goods. If, for instance, a car is sold from one household to another, then the transaction will not be taken into account in the HICP. If, by contrast, that car is first sold from a household to a car dealer, and then sold on to another household, then the price of that car is taken into account for the second-hand car price index¹. The reason behind this is that the car dealer adds a certain added value.

In 2016, the “owner-occupied house price index”, that follows this net acquisition approach, was published for the first time on Eurostat for all euro area countries except Greece. It does not only include purchase costs of houses (sections 1.1 and 1.2 in table 2), but also the services related to the acquisition (1.3 in the table), such as solicitors’ fees, estate agent fees, registration fees, etc. Next to this, ownership costs such as major repairs renovations (section 2.1 in table 2), insurances (2.2), and other expenditures such as energy efficiency and gas safety certificates, municipal or local annual property tax, etc. (2.3), are also included. In practice, the “net” principle for house purchases implies that mainly newly built houses are taken into account (either self-build, or “turnkey”

¹ For the weighting of second-hand cars, only the value added by the car dealer is taken into account (and not the price of the car) if the car originally comes from a household.

Table 2

Breakdown of Belgium’s owner-occupied house price index

	Weighting in 2021, in per thousand
1. Acquisitions of dwellings	863.2
1.1 New dwellings	744.6
1.1.1 Purchases of new dwellings	407.1
1.1.2 Self-build dwellings and major renovations	337.4
1.2 Existing dwellings new to the households	0.0
1.3 Other services related to the acquisition of dwellings	118.7
2. Ownership of dwellings	136.8
2.1 Major repairs and maintenance	98.5
2.2 Insurance connected with dwellings	38.3
2.3 Other expenditure	0.0
Total	1 000.0

Source: Eurostat.

properties). Transfers from firms (or the general government sector) to households imply, in practice, houses that were rented out before, and are now sold to be occupied by their owners. Still, in many countries (including Belgium), this category is non-existent, in most cases due to a shortage of reliable data sources or an insufficient number of transactions to compile a reliable price index. Note that the other services related to the acquisition of dwellings, such as the payment of registration duties, are taken into account regardless of whether the house being sold was in the hands of another household or not. That is, a registration fee is a transaction with (payment to) the government (another sector).

The owner-occupied house price index differs from the house price index (both series are published on Eurostat's website). The latter measures price increases on the residential real estate market (primary and secondary market). By contrast, the former excludes all transactions on the secondary market (transactions between households) but includes self-build dwellings (whose price trend in Belgium is equal to construction costs). Another difference is that the owner-occupied house price index also includes other services related to the acquisition of dwellings and ownership costs (this is not shown on chart 3).

Note that both indices, just like any other price index, imply a quality correction. That is, quality improvements should not be considered as a price increase (even though, in reality, they do imply a more expensive good). This could possibly be a reason why not only house price rises, but also the inflation rate in general, are perceived to be higher than measured by the official indices. That is, thicker insulation, solar panels, etc. need to be paid for, but due to the quality adjustments, these extra costs do not always imply an increase in the price index. It should also be noted that corrections for quality improvements are statistically challenging, but should be applied in any price index, as is the case in the HICP index. This can be illustrated by the price index for technological goods such as smartphones or laptops: actual prices of these goods can increase or remain constant, while their price index generally declines due to the statistical integration of rapid technological developments (quality improvements).

Chart 3

Relationship between the owner-occupied house price index, the house price index and the construction output price index in Belgium

Sources: Eurostat, Statistics Belgium.

Notes: On this chart, the owner-occupied house price index only shows the major components. Renovation costs, registration duties, insurance, etc. are not shown here.

Just like the “self-build dwellings and major renovations” component during the whole period, the “purchase of new dwellings” component followed the construction output price index (= excluding land prices) up to 2013 in Belgium. For harmonisation purposes, this was changed as of 2013, and the “purchase of new dwellings” was based on real estate transaction data from the General Administration of Patrimonial Documentation of the FPS Finance.

The major conceptual challenge of the net acquisition approach is that it comprises an investment element, which is in fact not in compliance with HICP principles, that measures consumer price movements. That is, the buyer does not only consider the consumption purposes that the building will serve; he/she will also take into account the possible price increases that it will mean when selling in the future. So, this is an investment component. Therefore, the ECB urges statisticians to further work on the methodology in order to separate the investment element that does not belong in the HICP. It could be argued that the land component – currently still partly in the OOH price index – is seen as the clearest investment element, because the value of land does not deteriorate over time / due to consumption. The dwelling – by contrast – does deteriorate due to consumption, so the consumer has to constantly invest more money in order to maintain the quality of the building. But, others argue that the price of land is economically relevant and should by no means be excluded. Knoll *et al.* (AER 2017) show that rising land prices have made the largest contribution to the global¹ house price boom that has taken place since World War II. For Belgium, they conclude that the rise in land prices accounts for 81 % of the house price boom over 1950-2012. In any case, separating the investment component from the consumer component in the price index should be done with caution. That is, in order to do so, imputations would have to be made, which would endanger the HICP requirement of only using

¹ They have investigated Denmark, Belgium, the Netherlands, Sweden, Switzerland, the United States, Australia, Norway, France, Canada, the United Kingdom, and Finland. The remaining part (i.e. the part that is not explained by land prices) is explained by the rise in real construction costs.

actual transaction prices. Note the exclusion of land is particularly difficult for the price index; it is already left out of the weightings. Besides, for the self-built dwellings component, the land component is also excluded in a number of countries (including in Belgium).

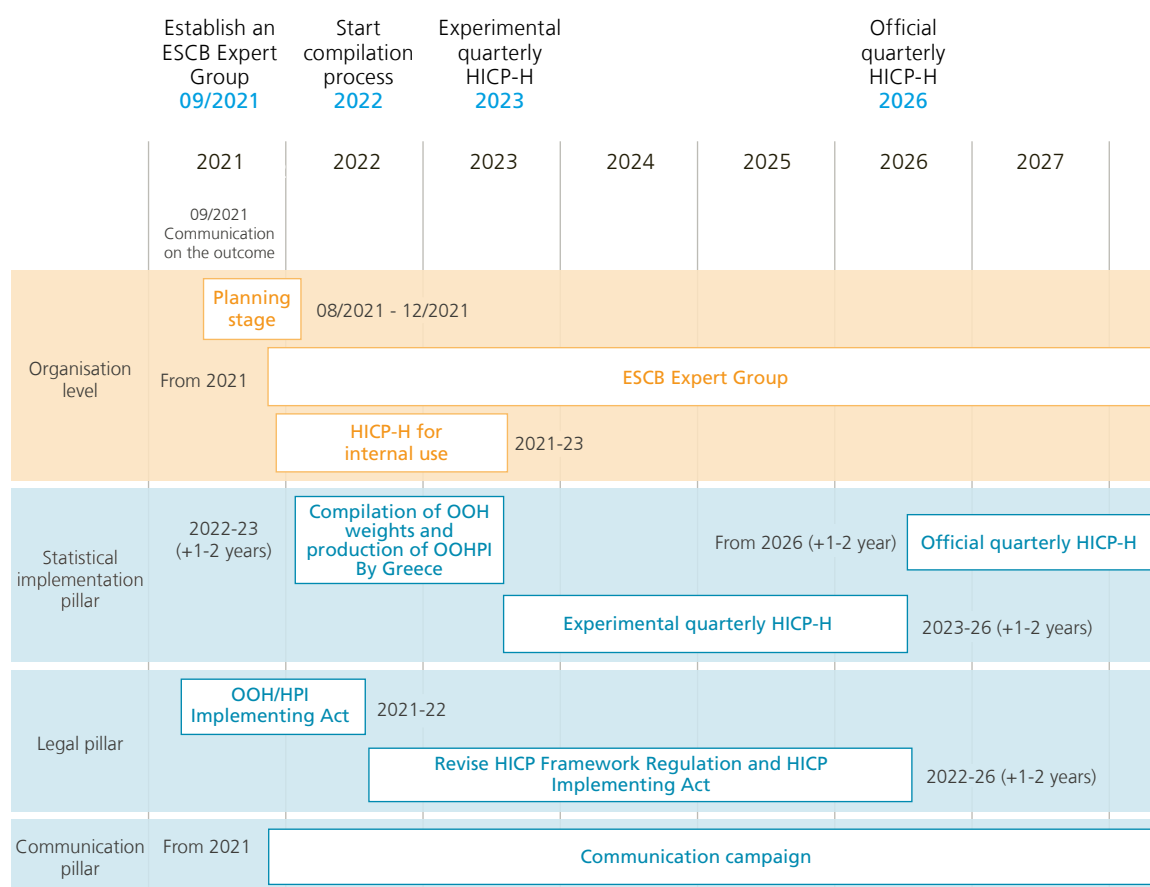

3.2 Proposed integration process under the net acquisition approach

Despite the challenges in the OOHPI such as the presence of an investment element, the ECB strategy review concluded that the net acquisition approach was the most appropriate method for including owner-occupied housing costs.

Integrating the owner-occupied house price index into the HICP index will be a process spanning a couple of years. First, even though the index is already published by Eurostat for (almost) all the countries, it needs to be further harmonised across countries. Second, the weight of the OOHPI in the HICP still needs to be determined. It may vary strongly with the house price/construction cycle so it might fluctuate strongly on a yearly basis. Based on household investment figures in the national accounts, the ECB (2022) estimates the weight of owner-occupied housing in the HICP to amount to about 10 % in Belgium and 9 % in the euro area. Third, the currently calculated

Chart 4

ECB's proposed roadmap for integrating owner-occupied housing into the HICP (HICP-H)

Source: ECB (Figure 3 in the ECB Occasional Paper "Inflation measurement and its assessment in the ECB's monetary policy strategy review").

OOHPI index is a quarterly index, whereas the HICP is monthly. Also, the OOHPI is published with a delay of about one quarter, while the HICP for the current month is available as early as the end of the next month. The delay of the former is caused by the late availability of the underlying data used to construct the OOHPI. For instance, data from the General Administration of Patrimonial Documentation (FPS Finance) are used. This information, in turn, is based on data coming from solicitors; who are given a certain time to report to the statistical offices.

The ECB strategy review proposes a possible roadmap for integrating owner-occupied housing into the HICP (called the HICP-H index). After the compilation of an OOHPI for Greece¹ and the weights of OOH in the HICP, it should be possible to publish experimental quarterly statistics for an HICP that includes owner-occupied housing (called HICP-H) at euro area level by 2023. It is experimental in the sense that regular revisions are possible as the methodology is being fine-tuned. In the meantime, the HICP Framework Regulation should be revised, to enable the OOHPI to be included. Finally, it should be possible for Eurostat to publish a fully qualitative quarterly HICP-H by 2026. However, the two problems mentioned before (timeliness and publishing delay) will probably not be tackled by this timeframe. This means that, until then, the ECB will continue to use the current HICP (monthly) as its main policy target, and will only consider the HICP-H as an additional indicator. It would be desirable to develop an HICP-H on a monthly basis, respecting the time schedule of the current HICP, but this is extremely challenging as its compilation would require the use of alternative data sources that are available faster than data from Patrimonial Documentation, for instance. A promising example of such alternative data sources could be web scraping, but this source faces other challenges. For instance, the asking price on a real estate website is not the same as the actual price (due to negotiations), and the fact that one house is typically presented on several property websites brings a risk of duplication. Also, the presence of the investment component should be excluded if owner-occupied housing becomes part of the official ECB inflation target.

4. Impact on inflation

4.1 Belgium

In some specific periods, the impact of integrating OOH can be considerable. For instance, in 2020, the inflation rate would have been 0.7% instead of 0.4%; a difference of 0.3 of a percentage point. Based on the first three quarters of 2021, the impact would even be 0.4 of a percentage point in that year. Throughout the COVID-19 pandemic, the house prices, that were already on the rise, were further influenced upwards by a number of factors. First, the demand for houses further increased, supported by lower bank lending rates as well as by higher household savings. Both factors might also have stimulated housing demand for investment purposes. Second, on the supply side, labour and material shortages exerted upwards pressures on construction costs and limited the construction of new houses (ECB, 2021c).

However, over the whole period considered, integrating owner-occupied housing in the Belgian HICP has a limited impact. There are several (technical) reasons for this, both in terms of the weight and in terms of the evolution of the price index. As regards the limited weight of OOH in the HICP, it can be explained, first, by the “net” principle (only purchase transactions between the household sector and another sector are taken into account, see below). That is, the weight is about 10% (both in Belgium and in the euro area), whereas many families spend a bigger share of their income to housing. Second, the component “land” is excluded from the OOH weight. Even though it is statistically not yet possible to exclude the land component from the price index of purchases of new dwellings (with data coming from Patrimonial Documentation), it is possible to exclude land from the weights (these are based on national accounts).

1 It should be recalled that Greece is the only euro area country that does not yet compile any owner-occupied house price statistics.

Chart 5

Impact of integrating owner-occupied housing into the Belgian HICP with the net acquisition approach

(year-on-year changes in the index in %, unless otherwise stated)

Sources: ECB calculations, Eurostat, Own calculations.

Note: The OOH weights are approximative and are based on calculations by ECB (2022). As the OOH weight for 2021 is not yet available, the 2020 weight has been used for the year 2021.

As regards the evolution of the price index: while the price index of owner-occupied housing indeed increases most of the time faster than the HICP index, the difference between the two series' evolution is not that substantial, especially up to 2018. The reason for this is, again, twofold. First, even though it is impossible to exclude land from the component "purchases of new dwellings" (turn-key houses), it is possible to exclude land

Chart 6

Owner-occupied house price index versus HICP index in Belgium

(2011Q1 = 100)

Source: Eurostat.

in the “self-build dwellings and major renovations” category. In other words, land is excluded from a significant part of the acquisition component index. That is the case in many countries, including Belgium. As Knoll et al (AER, 2017) argue that land prices are accountable for a big part of the total price increase, this could limit the price increase of the total index. Second, just like in any other index that reflects a price evolution, quality adjustments are made. That is, quality improvements that imply price increases, should not be considered as price increases. In practice, this means that, for example, stricter energy norms have to be considered as a quality improvement, hence they do not count as price increases. Still, the extra investment in solar panels, thick insulation, etc. still needs to be made and is perceived by the public as extra costs for building.

4.2 Euro area

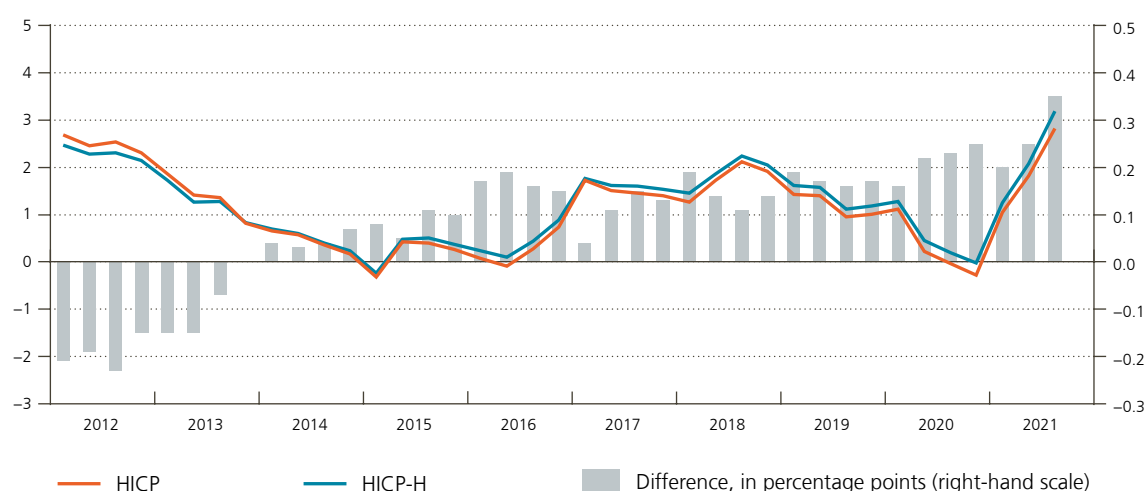

Just like in Belgium, the impact of integrating owner-occupied housing into the euro area HICP is rather limited over a longer time frame. At the start of the period under consideration (2012-2013), the inflation rate including owner-occupied housing would even have been lower than the current HICP inflation rate. Similarly, the impact in the more recent period is larger in the euro area (around 0.2 of a percentage point in 2020 and, based on the first three quarters, 0.3 in 2021), although it is smaller than in Belgium (0.3 of a percentage point in 2020 and, based on the first three quarters, 0.4 in 2021).

The reasons for the limited impact and the larger impact more recently are similar in both the euro area and Belgium. One should note that the weight of the OOHPI in the euro area (about 9 %) is estimated to be slightly smaller than in Belgium (about 10 %).

Chart 7

Impact of integrating owner-occupied housing into the euro area HICP with the net acquisition approach

(year-on-year changes in the index in %, unless otherwise stated)

Sources: ECB calculations, Eurostat, Own calculations.

Note: The OOH weights are approximative and are based on calculations by ECB (2022). As the OOH weight for 2021 is not yet available, the 2020 weight has been used for the year 2021.

Conclusion

The listening events held by the ECB and the national central banks revealed that the public is genuinely concerned about sharply rising house prices. Zekaite (2020) furthermore shows that consumers do think of housing costs in particular when they shape their inflation perceptions. Nevertheless, owner-occupied housing costs (such as property purchase) are not yet taken into account in the current inflation measure, the HICP index. To make the index more representative, the ECB decided in its 2020 strategy review to work together with Eurostat on integrating owner-occupied housing costs into the HICP index.

Two methods of possible inclusion of housing costs were considered during the strategy review, namely the rental equivalence approach and the net acquisition approach. The Governing Council deems the latter to be the best way of including housing costs, since it largely respects the HICP principles. An owner-occupied house price index (OOHPI) – which follows that approved approach – is already published by Eurostat. However, a major challenge is that it comprises an investment element, which should in fact be excluded from a consumer price index. Another challenge is that it is only a quarterly index (while the HICP is monthly) and it is published with a delay of one quarter (while the HICP for a given month is published around the 20th of the next month).

Overall, the impact of integrating owner-occupied housing costs into the HICP is limited. Several technical reasons explain this, both as regards the weight of the OOH component, and as regards the growth rate of its price index. For instance, use of a net approach, meaning that transactions on the secondary market (between households) are not taken on board, implies a limited weight of OOH in the HICP (it is estimated to be about 10 % in Belgium). Also, the land component, inflated by land prices rising faster than those of the buildings themselves, is fully excluded from the weighting. Besides, owner-occupied house price index growth could be lower than perceived by households, notably due to the fact that quality improvements to houses (such as the stricter norms for insulation) are corrected for (neutralised) when compiling a price index. Also, in Belgium as in most countries, the land part is excluded from a large component of the owner-occupied price index (self-build dwellings and major renovations). Nevertheless, in some specific periods, the inflation rate according to the HICP integrating housing costs differs substantially from the current HICP. That is the case in the most recent period, as during the COVID-19 crisis, average house prices were pushed up further. In 2020, the Belgian HICP inflation rate would have amounted to 0.7 % instead of the official 0.4 % had housing costs been included in the index.

The ECB proposes to move in phases towards an HICP inflation target that includes the OOHPI. Publishing a fully qualitative and harmonised statistic should be possible by 2026. By then, it will probably still be quarterly, and published with a delay, as the timing and feasibility of a monthly and timely OOHPI is still uncertain. For the time being, the existing HICP (monthly + published quickly) will remain the ECB's main monetary policy target, but the HICP integrating the OOHPI (quarterly + published with a delay) will serve as an auxiliary indicator.
